# **Table of contents**

Blind 75		3
1 - Two Sum - Easy		4
2 - Contains Duplicate - Easy		5
3 - Valid Anagram - Easy		6
4 - Group Anagrams - Medium		7
5 - Top K Frequent Elements - Medium		9
6 - Product of Array Except Itself - Medium	1	10
7 - Longest Consecutive Sequence - Medium	1	1
8 - Valid Palindrome - Easy	1	1
9 - Two Sum II - Input Array Is Sorted - Medium	1	12

# Blind 75

I want to improve my problem solving skills. I am starting with Blind 75.

Language Used - C++

# 1 - Two Sum - Easy

## **Notes**

The optimal solution uses a Unordered Map which is internally built using Hash Table concepts.

Usage of Hash Table enables the least cost of operations like search, delete, and insert.

```
class Solution {
public:
    vector<int> twoSum(vector<int>& nums, int target) {
        unordered_map<int, int> s;

        for (int i = 0; i < nums.size(); i++) {
            int com = target - nums[i];
            if (s.find(com) != s.end()) {
                return {s[com], i};
            }
            s.insert({nums[i], i});
        }
        return {};
    }
}</pre>
```

# 2 - Contains Duplicate - Easy

## **Notes**

The optimal solution uses a Unordered Set which is internally built using Hash Table concepts.

Usage of Hash Table enables the least cost of operations like search, delete, and insert.

```
class Solution {
public:
    bool containsDuplicate(vector<int>& nums) {
        unordered_set<int> us;

        for (int i : nums) {
            if (us.find(i) != us.end()) {
                return true;
            }
            us.insert(i);
        }

        return false;
    }
};
```

# 3 - Valid Anagram - Easy

## **Notes**

The optimal solution is to count the number of characters in each string for the 26 alphabets.

```
class Solution {
public:
    bool isAnagram(string s, string t) {
        if (s.size() != t.size()) {
            return false;
        }
        int c1[26] = \{0\};
        int c2[26] = \{0\};
        for (int i = 0; i < s.size(); i++) {</pre>
            c1[(s[i] - 97)]++;
            c2[(t[i] - 97)]++;
        }
        for (int i = 0; i < 26; i++) {
            if (c1[i] != c2[i]) {
                 return false;
            }
        }
        return true;
    }
};
```

# 4 - Group Anagrams - Medium

#### **Notes**

The optimal solution uses the same 26 alphabet count method but additionally uses a map to store the same type anagrams.

```
class Solution {
private:
    string getKey (string str) {
        vector<int> v(26,0);
        for (int i = 0; i < str.size(); i++) {</pre>
            v[str[i] - 'a']++;
        }
        string s = "";
        for (int i = 0; i < 26; i++) {
            s += '#' + to_string(v[i]);
        }
        return s;
    }
public:
    vector<vector<string>> groupAnagrams(vector<string>& strs) {
        unordered_map<string, vector<string>> um;
        for (int i = 0; i < strs.size(); i++) {</pre>
            string k = getKey(strs[i]);
            um[k].push_back(strs[i]);
        }
        vector<vector<string>> v;
        for (auto i = um.begin(); i != um.end(); i++) {
            v.push_back(i->second);
```

```
return v;
}
```

# 5 - Top K Frequent Elements - Medium

#### **Notes**

Usage of modified Bucket Sort approach which provides this optimal solution. This solution can also be done using Max Heap.

```
class Solution {
public:
    vector<int> topKFrequent(vector<int>& nums, int k) {
        unordered_map<int, int> um;
        for (int i = 0; i < nums.size(); i++) {</pre>
            um[nums[i]]++;
        }
        vector<vector<int>> v(nums.size() + 1);
        for (auto it = um.begin(); it != um.end(); it++) {
            v[it->second].push_back(it->first);
        }
        vector<int> result;
        for (int i = nums.size(); i >= 0; i--) {
            if (result.size() >= k) {
                return result;
            }
            if (v[i].size() != 0) {
                result.insert(result.end(), v[i].begin(), v[i].end());
            }
        }
        return {};
    }
};
```

# 6 - Product of Array Except Itself - Medium

## Notes

The optimal solution is using a prefix and a postfix to parse through the array from both sides and multiplying.

```
class Solution {
public:
    vector<int> productExceptSelf(vector<int>& nums) {
        vector<int> result(nums.size(), 1);
        int pre = 1;
        int post = 1;
        for (int i = 0; i < nums.size(); i++) {</pre>
            result[i] = result[i] * pre;
            pre = pre * nums[i];
        }
        for (int i = nums.size() - 1; i >= 0; i--) {
            result[i] = result[i] * post;
            post = post * nums[i];
        }
        return result;
    }
};
```

# 7 - Longest Consecutive Sequence - Medium

#### **Notes**

The optimal solution makes use of Unordered Set which provides an efficient way to search consecutive elements to find the Longest Consecutive Sequence.

#### **Program**

```
class Solution {
public:
    int longestConsecutive(vector<int>& nums) {
        unordered_set<int> s;
        copy(nums.begin(), nums.end(), inserter(s, s.end()));
        int longest = 0;
        for (int i = 0; i < nums.size(); i++) {</pre>
            int length = 0;
            if (s.find(nums[i] - 1) == s.end()) {
                length++;
                while (s.find(nums[i]+length) != s.end()) {
                     length++;
                longest = max(length, longest);
            }
        }
        return longest;
    }
};
```

# 8 - Valid Palindrome - Easy

#### **Notes**

This problem can be approached in multiple ways. Mine is one of them.

## **Program**

```
class Solution {
  public:
    bool isPalindrome(string s) {
        string t = "";

        for (auto i:s) {
            if (iswalnum(i)) t += i;
        }

        transform(t.begin(), t.end(), t.begin(), ::tolower);

        s = t;
        std::reverse(s.begin(), s.end());

        cout << s << endl << t << endl;
        if (s == t) return true;
        return false;
    }
};</pre>
```

# 9 - Two Sum II - Input Array Is Sorted - Medium

#### **Notes**

The optimal solution is to use the Two Pointer approach. Where one pointer from index 0 and the other pointer at the last index of the array.

```
class Solution {
public:
    vector<int> twoSum(vector<int>& nums, int target) {
        int i = 0;
        int j = nums.size() - 1;

        while (i < j) {</pre>
```
